# **GSERM** - **Oslo 2019**Panel/TSCS Data + Unit Effects

January 7, 2019 (morning session)

#### **Preliminaries**

- Instructor: Prof. Christopher Zorn (zorn@psu.edu).
- Class: January 7-11, 2019, 9:30-3:00 CET, at the Norwegian Business School.
- The course outline / syllabus is <a href="here">here</a>.
- More important: Slides, readings, code, etc. are on the course github repo

(https://github.com/PrisonRodeo/GSERM-Oslo-2019-git).

#### Software

#### R

- All examples, plots, etc.
- Current version is 3.5.2
- Packages you'll use (see the <u>econometrics</u> and <u>survival analysis</u> task views for more):
  - · plm
  - · lme4
  - · gee
  - survival (nearly everything you need)
  - · eha
  - · timereg

#### Stata

- Current version is 15.1.
- Mostly use the -xt- and -st- series of commands (for "cross-sectional time series" and "survival time")

#### Starting Points

- "Longitudinal" ≠ "Time Series"
- Terminology:
  - "Unit" / "Units" / "Units of observation" / "Panels" = Things we observe repeatedly
  - "Observations" = Each (one) measurement of a unit
  - "Time points" = When each observation on a unit is made
  - $i \in \{1...N\}$  indexes units
  - $t \in \{1...T\}$  or  $\{1...T_i\}$  indexes observations / time points
  - If  $T_i = T \ \forall i$  then we have "balanced" panels / units
  - NT = Total number of observations (if balanced)
- Averages:
  - $\bullet$   $Y_{it}$  indicates a variable that varies over both units and time,
  - $\bar{Y}_i = \frac{1}{T} \sum_{t=1}^{T} Y_{it}$  = the over-time mean of Y,
  - $\bar{Y}_t = \frac{1}{N} \sum_{i=1}^N Y_{it}$  = the across-unit mean of Y, and
  - $\bar{Y} = \frac{1}{NT} \sum_{i=1}^{N} \sum_{t=1}^{T} Y_{it}$  = the grand mean of Y.

## More Terminology

- $N >> T \rightarrow$  "panel" data
  - (American) National Election Study panel studies (N = 2000, T = 3)
  - (U.S.) Panel Study of Income Dynamics ( $N = \text{large}, T \approx 12$ )
- T >> N or  $T \approx N \rightarrow$  "time-series cross-sectional" ("TSCS") data
- $N=1 \rightarrow$  "time series" data

# ${\sf Panel/TSCS}\ {\sf Data}\ {\sf Structure}$

id	t	Y	$X_1$	
1	1	250	3.4	
1	2	290	3.3	
:	:	:	:	
2	1	160	4.7	
2	2	150	4.9	
:	:	:	:	
	•	•	•	•••

# Variation: A Tiny (Fake) Example

id	year	gender	pres	pid	approve
1	1998	female	clinton	dem	3

1	2002	female	bush	dem	5
1	2004	female	bush	dem	3
2 2 2 2 2	1998 2000 2002 2004	male male male male	clinton clinton bush bush	gop gop gop gop	2 1 4 3
3	1998	male	clinton	gop	2
3	2000	male	clinton	gop	2
3	2002	male	bush	gop	4
3	2004	male	bush	dem	1

# Aggregation: Cross-Sectional

1 female ? dem 3.50 2 male ? gop 2.50 3 male ? ? 2.25	id	gender	pres	pid	approve
	_	male	?	gop	2.50

# Aggregation: Temporal

1998       0.33       clinton       0.66(?)       2.33         2000       0.33       clinton       0.66(?)       2.00         2002       0.33       bush       0.66(?)       4.33         2004       0.33       bush       0.33(?)       2.33	year	female	pres	pid	approve
	2000 2002	0.33	clinton bush	0.66(?) 0.66(?)	2.00 4.33

#### The Point

#### Aggregation:

- Loses information
- Distorts relationships
- Forces arbitrary decisions

If you have variation in multiple dimensions, use it.

#### Within- and Between-Unit Variation

Define:

$$\bar{Y}_i = \frac{1}{T_i} \sum_{t=1}^{T_i} Y_{it}$$

Then:

$$Y_{it} = \bar{Y}_i + (Y_{it} - \bar{Y}_i).$$

- The total variation in  $Y_{it}$  can be decomposed into
- ullet The between-unit variation in the  $ar{Y}_i$ s, and
- The within-unit variation around  $\bar{Y}_i$  (that is,  $Y_{it} \bar{Y}_i$ ).

## Variation (U.S. Supreme Court Tenure)

#### "Total" Variation:

```
> with(scotus, describe(service))
          n mean sd median trimmed mad min max range skew kurtosis
   1 1765 11.74 8.34
                        10 10.93 8.9 1 37 36 0.73 -0.28
   se
X1 0.2
"Between" Variation:
> scmeans <- ddply(scotus,.(justice),summarise,
                  service = mean(service))
> with(scmeans, describe(service))

          n mean sd median trimmed mad min max range skew kurtosis
   1 1765
               0 6.92
                          Ω
                                  0.6.67 -18 18
                                                 36
                                                              -0.36
    Se
X1 0 16
```

#### Regression!

#### Model

$$Y_i = \beta_0 + \beta_1 X_i + u_i$$

#### assumes:

- All the usual OLS assumptions, plus
- $\beta_{0i} = \beta_0 \forall is$
- $\beta_{1i} = \beta_1 \ \forall \ is$

$$Y_{it} = \beta_0 + \beta_1 X_{it} + u_{it}$$

(same)

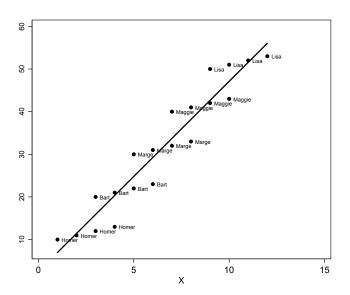

## Variable Intercepts

$$Y_{it} = \beta_{0i} + \beta_1 X_{it} + u_{it}$$

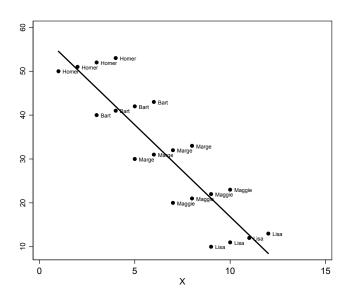

$$Y_{it} = \beta_{0t} + \beta_1 X_{it} + u_{it}$$

$$Y_{it} = \beta_{0it} + \beta_1 X_{it} + u_{it}$$

# Varying Intercepts

## Varying Intercepts

# Varying Slopes (+ Intercepts)

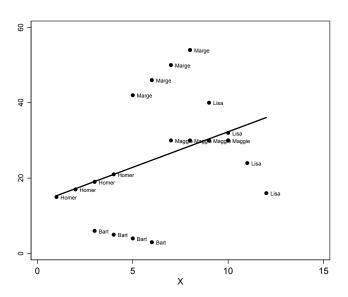

$$Y_{it} = \beta_0 + \beta_{1i} X_{it} + u_{it}$$

$$Y_{it} = \beta_{0i} + \beta_{1i} X_{it} + u_{it}$$

$$Y_{it} = \beta_{0t} + \beta_{1t} X_{it} + u_{it}$$

$$Y_{it} = \beta_{0it} + \beta_{1it}X_{it} + u_{it}$$

# ${\sf Varying\ Slopes}\,+\,{\sf Intercepts}$

#### The Error

$$u_{it} \sim \text{i.i.d.} N(0, \sigma^2) \ \forall \ i, t$$

$$Var(u_{it}) = Var(u_{jt}) \ \forall \ i \neq j \ (i.e., no cross-unit heteroscedasticity)$$
  
 $Var(u_{it}) = Var(u_{is}) \ \forall \ t \neq s \ (i.e., no temporal heteroscedasticity)$   
 $Cov(u_{it}, u_{is}) = 0 \ \forall \ i \neq j, \ \forall \ t \neq s \ (i.e., no auto- or spatial correlation)$ 

## Pooling

- Adds data
- Generalizability

$$Y_{it} = \beta_0 + \beta_1 X_{it} + u_{it}$$

#### **Implies**

- that the process governing the relationship between X and Y is exactly the same for each i,
- that the process governing the relationship between X and Y is the same for all t,
- that the process governing the us is the same  $\forall i$  and t as well.

# "Partial" Pooling (Bartels 1996)

Two regimes:

$$Y_A = \beta_A' \mathbf{X}_A + u_A$$

$$Y_B = \beta_B' \mathbf{X}_B + u_B$$

with  $\sigma_A^2 = \sigma_B^2$ , and  $Cov(u_A, u_B) = 0$ .

Estimators:

$$\hat{\beta}_{A,B} = (\mathbf{X}'_{A,B}\mathbf{X}_{A,B})^{-1}\mathbf{X}'_{A,B}Y_{A,B}$$

and

$$\widehat{\mathsf{Var}(eta_{A,B})} = \hat{\sigma}_{A,B}^2(\mathbf{X}_{A,B}'\mathbf{X}_{A,B})^{-1},$$

#### A Pooled Estimator

$$\hat{\beta}_{P} = (\mathbf{X}'_{A}\mathbf{X}_{A} + \mathbf{X}'_{B}\mathbf{X}_{B})^{-1}(\mathbf{X}'_{A}Y_{A} + \mathbf{X}'_{B}Y_{B}) 
= (\mathbf{X}'_{A}\mathbf{X}_{A} + \mathbf{X}'_{B}\mathbf{X}_{B})^{-1}[\beta_{A}(\mathbf{X}'_{A}\mathbf{X}_{A}) + \beta_{B}(\mathbf{X}'_{B}\mathbf{X}_{B})],$$

$$E(\hat{\beta}_P) = \beta_A + (\mathbf{X}_A'\mathbf{X}_A + \mathbf{X}_B'\mathbf{X}_B)^{-1}\mathbf{X}_B'\mathbf{X}_B(\beta_B - \beta_A)$$
$$= \beta_B + (\mathbf{X}_A'\mathbf{X}_A + \mathbf{X}_B'\mathbf{X}_B)^{-1}\mathbf{X}_A'\mathbf{X}_A(\beta_A - \beta_B)$$

#### Pooling: Tests

$$F = \frac{\frac{\hat{\mathbf{u}}_{P}'\hat{\mathbf{u}}_{P} - (\hat{\mathbf{u}}_{A}'\hat{\mathbf{u}}_{A} + \hat{\mathbf{u}}_{B}'\hat{\mathbf{u}}_{B})}{K}}{\frac{(\hat{\mathbf{u}}_{A}'\hat{\mathbf{u}}_{A} + \hat{\mathbf{u}}_{B}'\hat{\mathbf{u}}_{B})}{(N_{A} + N_{B} - 2K)}} \sim F_{[K,(N_{A} + N_{B} - 2K)]}$$

## Fractional Pooling

$$\hat{\beta}_{\lambda} = (\lambda^2 \mathbf{X}_A' \mathbf{X}_A + \mathbf{X}_B' \mathbf{X}_B)^{-1} (\lambda^2 \mathbf{X}_A' Y_A + \mathbf{X}_B' Y_B)$$

with  $\lambda \in [0,1]$ :

- $\lambda=0$  ightarrow separate estimators for  $\hat{eta}_{A}$  and  $\hat{eta}_{B}$ ,
- $\lambda = 1 \rightarrow$  "fully pooled" estimator  $\hat{\beta}_P$ ,
- $0 < \lambda < 1 \rightarrow$  a regression where data in regime A are given some "partial" weighting in their contribution towards an estimate of  $\beta$ .

## Pooling, Summarized

"(R)oughly speaking, it makes sense to pool disparate observations if the underlying parameters governing those observations are sufficiently similar, but not otherwise."

- Bartels (1996)

# "Unit Effects"

## One- and Two-Way Unit Effects

Two-way variation:

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + \gamma V_i + \delta W_t + u_{it}$$

 $\longrightarrow$  two-way effects:

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + \alpha_i + \eta_t + u_{it}$$

One-way effects:

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + \eta_t + u_{it}$$
 (time)

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + \alpha_i + u_{it}$$
 (units)

"Brute force" model:

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + \alpha_i + u_{it}$$
  
=  $\mathbf{X}_{it}\boldsymbol{\beta} + \alpha_1 I(i=1)_i + \alpha_2 I(i=2)_i + ... + u_{it}$ 

Alternatively:

$$\bar{X}_i = \frac{\sum_{N_i} X_{it}}{N_i}$$

and

$$\tilde{X}_{it} = X_{it} - \bar{X}_i$$
.

Yields:

$$Y_{it} = \bar{\mathbf{X}}_i \beta_B + (\mathbf{X}_{it} - \bar{X}_i) \beta_W + \alpha_i + u_{it}$$

#### "Fixed" Effects

Means that:

$$Y_{it}^* = Y_{it} - \bar{Y}_i$$
  
 $\mathbf{X}_{it}^* = \mathbf{X}_{it} - \bar{\mathbf{X}}_i$ 

$$Y_{it}^* = \beta_{FE} \mathbf{X}_{it}^* + u_{it}.$$

≡ "Within-Effects" Model.

"Fixed" Effects: Test(s)

Standard F-test for

$$H_0: \alpha_i = \alpha_j \forall i \neq j$$

versus

$$H_A: \alpha_i \neq \alpha_j$$
 for some  $i \neq j$ 

is 
$$\sim F_{N-1,NT-(N-1)}$$
.

#### Data:

- 50 African countries  $\rightarrow$  (50  $\times$  49 = ) 2450 directed dyads
- Ten years
- i indexes directed dyads, t indexes years

#### Model:

```
ln(\mathsf{Refugees})_{A \to Bt} = \beta_0 + \beta_1 \mathsf{Population} \; \mathsf{Difference}_{ABt} + \beta_2 \mathsf{Distance}_{AB} + \beta_3 \mathsf{POLITY} \; \mathsf{Difference}_{ABt} + \beta_4 \mathsf{War} \; \mathsf{Difference}_{ABt} + u_{ABt}
```

## Data: Refugee Flows in Africa, 1992-2001

# Issues (?) with "Fixed" Effects

#### Pros:

- Specification Bias
- Intuitive
- Widely Used/Understood

#### Cons:

- Can't Estimate  $\beta_B$
- Slowly-Changing Xs
- (In)Efficiency / Inconsistency ("Incidental Parameters")

## "Between" Effects

From:

$$Y_{it} = \bar{\mathbf{X}}_i \beta_B + (\mathbf{X}_{it} - \bar{\mathbf{X}}_i) \beta_W + \alpha_i + u_{it}.$$

"Between" effects:

$$\bar{Y}_i = \bar{\mathbf{X}}_i \boldsymbol{\beta}_B + u_{it}$$

- Essentially cross-sectional
- Based on N observations

# Refugee Example Redux

		Fixed	Between
Variable	OLS	("Within") Effects	Effects
Constant	-0.32	-	-0.30
	(0.01)		(0.03)
Population Difference	-0.17	6.86	-0.25
	(0.22)	(2.55)	(0.53)
Distance	-0.13	(dropped)	-0.13
	(0.005)		(0.01)
POLITY Difference	-0.0002	0.005	0.01
	(0.016)	(0.022)	(0.05)
War Difference	0.074	0.010	0.12
	(0.007)	(0.007)	(0.02)
$\hat{ ho}$	<u> </u>	0.61	

Note: NT = 23618 (N = 2450,  $\bar{T} = 9.6$ ).

Model:

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + u_{it}$$

with:

$$u_{it} = \alpha_i + \lambda_t + \eta_{it}$$

and

$$\begin{split} E(\alpha_i) &= E(\lambda_t) = E(\eta_{it}) &= 0, \\ E(\alpha_i \lambda_t) &= E(\alpha_i \eta_{it}) = E(\lambda_t \eta_{it}) &= 0, \\ E(\alpha_i \alpha_j) &= \sigma_\alpha^2 \text{ if } i = j, \ 0 \text{ otherwise}, \\ E(\lambda_t \lambda_s) &= \sigma_\lambda^2 \text{ if } t = s, \ 0 \text{ otherwise}, \\ E(\eta_{it} \eta_{js}) &= \sigma_\eta^2 \text{ if } i = j, \ t = s, \ 0 \text{ otherwise}, \\ E(\alpha_i \mathbf{X}_{it}) &= E(\lambda_t \mathbf{X}_{it}) = E(\eta_{it} \mathbf{X}_{it}) &= 0. \end{split}$$

## "Random" Effects

"Variance Components":

$$Var(Y_{it}|\mathbf{X}_{it}) = \sigma_{\alpha}^2 + \sigma_{\lambda}^2 + \sigma_{\eta}^2$$

If we assume  $\lambda_t = 0$ , then we get a model like:

$$Y_{it} = \mathbf{X}_{it}\beta + \alpha_i + \eta_{it}$$

with total error variance:

$$\sigma_{\it u}^2 = \sigma_{\alpha}^2 + \sigma_{\eta}^2.$$

## "Random" Effects: Estimation

$$\begin{split} E(\mathbf{u}_i \mathbf{u}_i') &\equiv \mathbf{\Sigma}_i &= \sigma_{\eta}^2 \mathbf{I}_T + \sigma_{\alpha}^2 \mathbf{i} \mathbf{i}' \\ &= \begin{pmatrix} \sigma_{\eta}^2 + \sigma_{\alpha}^2 & \sigma_{\alpha}^2 & \cdots & \sigma_{\alpha}^2 \\ \sigma_{\alpha}^2 & \sigma_{\eta}^2 + \sigma_{\alpha}^2 & \cdots & \sigma_{\alpha}^2 \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{\alpha}^2 & \sigma_{\alpha}^2 & \cdots & \sigma_{\eta}^2 + \sigma_{\alpha}^2 \end{pmatrix} \\ \text{Var}(\mathbf{u}) &\equiv \mathbf{\Omega} = \begin{pmatrix} \mathbf{\Sigma}_1 & 0 & \cdots & 0 \\ 0 & \mathbf{\Sigma}_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \mathbf{\Sigma}_N \end{pmatrix} \end{split}$$

## "Random" Effects: Estimation

Can estimate:

$$oldsymbol{\Sigma}^{-1/2} = rac{1}{\sigma_{\eta}} \left[ oldsymbol{I}_{\mathcal{T}} - \left( rac{ heta}{\mathcal{T}} oldsymbol{ii}' 
ight) 
ight]$$

where

$$heta = 1 - \sqrt{rac{\sigma_{\eta}^2}{T\sigma_{lpha}^2 + \sigma_{\eta}^2}}.$$

With  $\hat{\theta}$ , calculate:

$$Y_{it}^* = Y_{it} - \hat{\theta} \bar{Y}_i$$
  
$$X_{it}^* = X_{it} - \hat{\theta} \bar{X}_i,$$

estimate:

$$Y_{it}^* = (1 - \hat{ heta}) lpha + X_{it}^* eta_{RE} + [(1 - \hat{ heta}) lpha_i + (\eta_{it} - \hat{ heta} ar{\eta}_i)]$$

and iterate...

# "Random" Effects: Testing

Hausman test (FE vs. RE):

$$\hat{\mathcal{W}} = (\hat{\beta}_{\mathsf{FE}} - \hat{\beta}_{\mathsf{RE}})'(\hat{\mathbf{V}}_{\mathsf{FE}} - \hat{\mathbf{V}}_{\mathsf{RE}})^{-1}(\hat{\beta}_{\mathsf{FE}} - \hat{\beta}_{\mathsf{RE}})$$

$$W \sim \chi_k^2$$

#### Issues:

- Asymptotic
- No guarantee  $(\hat{f V}_{\sf FE} \hat{f V}_{\sf RE})^{-1}$  is positive definite
- A general specification test...

## Hausman Test

### Hausman test (FE vs. RE):

> phtest(RefFE, AltRefRE)

#### Hausman Test

data: ln\_ref\_flow ~ pop\_diff + distance + regimedif + wardiff
chisq = 34.712, df = 3, p-value = 0.0000001401
alternative hypothesis: one model is inconsistent

# Practical "Fixed" vs. "Random" Effects

- "Panel" vs. "TSCS" Data
- Data-Generating Process
- Covariate Effects

# Separating Within and Between Effects

$$Y_{it} = \mathbf{\bar{X}}_i \boldsymbol{eta}_B + (\mathbf{X}_{it} - \mathbf{\bar{X}}_i) \boldsymbol{eta}_W + u_{it}$$

- Simple...
- Easy interpretation
- Easty to test  $\hat{oldsymbol{eta}}_B = \hat{oldsymbol{eta}}_W$

# Again With The Refugees...
